

Simulation de mobilité sur NetLogo

1- Vehicle movement update

- Vehicles now follow the graph using face next-node + fd distance.
- If a vehicle reaches a waypoint during a tick, it immediately continues toward the next one.
- This avoids artificial slowdowns at every node.

2. Speed and simulated time

- Speed is converted from km/h to NetLogo units per tick.
- Added the simulated clock with sim-time-seconds.
- Current limitation: the spatial scale still needs calibration through meters-per-netlogo-unit.
- PD: calibrate real campus distance vs. NetLogo units.

Simulation de mobilité sur NetLogo

3. Destination handling fix

- Fixed the issue where vehicles continued driving after reaching their final destination.
- Added an arrived? state to identify vehicles that have completed their route.

4. First congestion logic

- Vehicles check their future position before moving.
- If another vehicle is too close, the vehicle stops temporarily.
- Added basic safety distances for roads and intersections.
- Added a simple priority rule using who to avoid permanent deadlocks.
