

Continuous Traffic Simulation

- Added a continuous simulation mode with a configurable duration.
- Vehicles are generated automatically during the simulation.
- Each vehicle receives a random origin and destination.
- A shortest path is computed for each generated vehicle.
- Vehicles are removed once they reach their destination.
- Added basic indicators: generated vehicles, completed trips, active vehicles and failed paths.

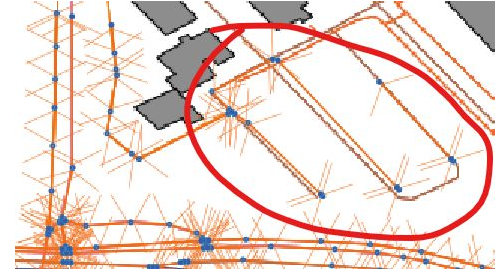

Congestion Logic and Network Restrictions

- Improved the basic congestion logic to reduce vehicle overlapping.
- Tested priority rules for intersections and roundabouts.
- The current priority logic is not fully reliable yet.
- Some vehicles can still get blocked or fail to follow the intended priority rule.
- This shows that traffic interaction needs further refinement.
- Temporarily disabled mode-based filtering until coherent SHP files are available.
- Next step: refine congestion rules and use unified SHP files for transport-mode restrictions.
